Pairing function. Diagonalization.

# Relations

Remember that a relation is a subset of the Cartesian Product of two sets.

For example,

$$R = \{(a, b) \in A \times B \mid \text{some property holds}\}$$

$$R \subseteq A \times B$$

For convenience, we adopt the following infix notation:

when  $(a, b) \in R$ , we write  $aRb$

Theorem

# Relations. Infix notation

## Relations

Partial orders

Infinite sets

Countable sets

Hilbert's Hotel

Ordered pairs

Power set.  
Diagonalization.

Schröder-Bernstein  
Theorem

It is originated from the relations like  $=$ ,  $\leq$ ,  $\geq$ ,  $<$ , and  $>$ .

$(1, 2) \in R_{(<)}$  we usually write  $1 < 2$

$(3, 3) \in R_{(=)}$  we usually write  $3 = 3$

Divisibility is a relation on  $\mathbb{N}$  too. And we use infix notation:

$(15, 60) \in R_{(divides)}$  we write  $15 \mid 60$

# Relations on the same set

## Relations

Partial orders

Infinite sets

Countable sets

Hilbert's Hotel

Ordered pairs

Power set.

Diagonalization.

Schröder-Bernstein  
Theorem

What if the sets  $A$  and  $B$  are the same?

$$R \subseteq A \times A$$

For example,  $=$ ,  $\leq$ ,  $\geq$ ,  $<$ ,  $>$  are relations on  $\mathbb{N}$ . That is, these relations are subsets of  $\mathbb{N} \times \mathbb{N}$ .

**Def.** A relation on the set  $A$  is

- *reflexive* if  $\forall x \in A : xRx$ .
- *symmetric* if  $\forall x, y \in A : xRy \rightarrow yRx$ .
- *antisymmetric* if  $\forall x, y \in A : (xRy \wedge yRx) \rightarrow x = y$ .
- *transitive* if  $\forall x, y, z \in A : (xRy \wedge yRz) \rightarrow xRz$ .

# Relations on the same set

## Relations

Partial orders

Infinite sets

Countable sets

Hilbert's Hotel

Ordered pairs

Power set.  
Diagonalization.

Schröder-Bernstein  
Theorem

- *reflexive* if  $\forall x \in A : xRx$ .
- *symmetric* if  $\forall x, y \in A : xRy \rightarrow yRx$ .
- *antisymmetric* if  $\forall x, y \in A : (xRy \wedge yRx) \rightarrow x = y$ .
- *transitive* if  $\forall x, y, z \in A : (xRy \wedge yRz) \rightarrow xRz$ .

	reflexive?	symmetric?	antisymmetric?	transitive?
$x \equiv y \pmod{5}$	Yes	Yes	No	Yes
$x \mid y$	Yes	No	Yes	Yes
$x \leq y$	Yes	No	Yes	Yes

# Partial orders

**Def.** A relation is a *partial order* if it is reflexive, antisymmetric, and transitive.

An example, the “divides” relation on the natural numbers is a partial order:

- It is reflexive because  $x \mid x$ .
- It is antisymmetric because  $x \mid y$  and  $y \mid x$  implies  $x = y$ .
- It is transitive because  $x \mid y$  and  $y \mid z$  implies  $x \mid z$ .

The  $\leq$  relation on the natural numbers is also a partial order. However, the  $<$  relation is not a partial order, because it is not reflexive; no number is less than itself.

Schröder-Bernstein  
Theorem

# Partial orders

Relations

Partial orders

Infinite sets

Countable sets

Hilbert's Hotel

Ordered pairs

Power set.  
Diagonalization.

Schröder-Bernstein  
Theorem

Often a partial order relation is denoted with the symbol

$$\preceq$$

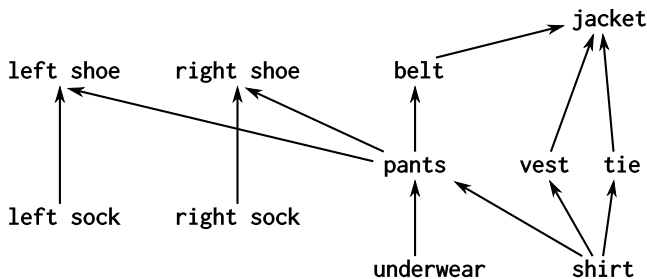

instead of a letter, like  $R$ .

This makes sense since the symbol calls to mind  $\leq$ , which is one of the most common partial orders.

$x \preceq y$  it reads as “ $x$  precedes  $y$ ”.

# Partially ordered sets

**Def.** If  $\preceq$  is a partial order on the set  $A$ , then the pair  $(A, \preceq)$  is called a *partially-ordered set* or *poset*.

**Def.** The elements  $x$  and  $y$  of a poset  $(A, \preceq)$  are called *comparable* if either  $x \preceq y$  or  $y \preceq x$ .

When  $x$  and  $y$  are elements of  $A$  such that neither  $x \preceq y$  nor  $y \preceq x$ ,  $x$  and  $y$  are called *incomparable*.

Diagonalization.

Schröder-Bernstein  
Theorem

# Partially ordered sets

**Theorem.** A poset  $(A, \preceq)$  has no directed cycles other than self-loops, that is, there is no sequence of  $n \geq 2$  distinct elements  $a_i \in A$  such that

$$a_1 \preceq a_2 \preceq a_3 \preceq a_4 \preceq \dots \preceq a_{n-1} \preceq a_n \preceq a_1$$

*Proof.* Suppose that for some  $n \geq 2$  such sequence  $a_1 \dots a_n$  exists.

Recall that the partial order is a transitive, antisymmetric, and reflexive relation.

Since it's transitive:  $a_1 \preceq a_2$  and  $a_2 \preceq a_3$ , therefore  $a_1 \preceq a_3$ .

Similarly, we prove that  $a_1 \preceq a_4$ ,  $a_1 \preceq a_5$ , ...,  $a_1 \preceq a_n$ .

Thus  $a_1 \preceq a_n$  and  $a_n \preceq a_1$ .

But  $\preceq$  is antisymmetric, and therefore  $a_1 = a_n$ . This contradicts the supposition that  $a_1, \dots, a_n$  are  $n \geq 2$  distinct elements! Thus there is no such directed cycle.

Relations

Partial orders

Infinite sets

Countable sets

Hilbert's Hotel

Ordered pairs

Power set.  
Diagonalization.

Schröder-Bernstein  
Theorem

# Total order

**Def.** A *total order* is a partial order in which every pair of elements is comparable.

$(A, \preceq)$  is a total order if for every  $x, y \in A$ , either  $x \preceq y$  or  $y \preceq x$ .

The  $\leq$  relation on natural numbers is a total order. However, the “divides” relation on the same set  $\mathbb{N}$  is not.

*Question:* Given a partially ordered set  $(A, \preceq)$ , can we make a total order  $\preceq_T$  that is “compatible” with the given partial order  $\preceq$ ? (Compatible in the sense that the total order never violates the given partial order)

...							
$C$	1	0	0	1	1	0	...

We construct a counter-example set  $C$  that is different from each subset  $A_i$ . How can we do it?

For all  $i = 0, 1, 2, 3, \dots$ : Whenever  $i \in A_i$ , we choose  $i \notin C$ , and vice versa, when  $i \notin A_i$ , we choose  $i \in C$ . Thus, by construction,  $C$  is different from each  $A_i$ . Effectively, the set  $C$  inverts the diagonal.

Schröder-Bernstein  
Theorem

# Power set

Since  $C \neq A_i$  for all  $i$ , and  $C$  is obviously a subset of  $\mathbb{N}$  by construction, the list of subsets  $A_i$  does not contain all subsets of  $\mathbb{N}$  (it does not contain  $C$ , for example), therefore, our assumption was incorrect: the subsets of  $\mathbb{N}$  are not countable.

That is, *the power set  $\mathcal{P}(\mathbb{N})$  is uncountable.* □

This proof strategy is called diagonalization.

Similarly, we can show that the *unit interval*  $0 \leq x \leq 1$  of real numbers is uncountable. (Also, see Rosen's book for the proof). And because you can make a bijection between this interval,  $[0, 1]$ , and  $\mathbb{R}$ , the set of all real number is uncountable.

Theorem

# More results about cardinality

**Theorem.** If  $A$  and  $B$  are countable sets, then their union  $A \cup B$  is also countable.

*Proof.* Without loss of generality, we can assume that  $A$  and  $B$  are disjoint. (If they are not, we continue the proof with  $A$  and  $B \setminus A$ )

If at least one of the sets is finite, we first list this set, then the other set.

Otherwise, if both are infinite countable sets, we list both sets by alternating elements:

$$a_0, b_0, a_1, b_1, a_2, b_2, \dots$$

where  $a_i \in A$  and  $b_i \in B$ .

Theorem

## Mapping rules

If there is a *one-to-one* function  $f : A \rightarrow B$  then

$$|A| \leq |B|.$$

If there is an *onto* function  $g : A \rightarrow B$  then

$$|A| \geq |B|.$$

If there is a *bijection*  $h : A \rightarrow B$  then

$$|A| = |B|.$$

Schröder-Bernstein  
Theorem

**Theorem** (Schröder-Bernstein). Given two sets  $A$  and  $B$ , if there exist one-to-one functions  $f : A \rightarrow B$  and  $g : B \rightarrow A$ , then there is a bijection between  $A$  and  $B$ .

In other words, to prove existence of a bijection, it's enough to prove existence of two one-to-one functions:

Once you have found a one-to-one function  $f : A \rightarrow B$ , instead of proving that  $f$  is onto, you can prove that there exists another one-to-one function that maps  $B$  to  $A$ .
