

# Trees

# Tree

**Def.** A *tree* is a connected undirected graph with no simple cycles.

It does not need to have a root node, or directed edges. So, it is not hierarchical, and there are no parent/child nodes.

**Theorem.** There is *exactly one simple path* between each pair of vertices in a tree.

Assume that there are two different simple paths from  $x$  to  $y$ .

Can we prove that it cannot happen in a tree?

# Uniqueness of a simple path

**Theorem.** There is *exactly one simple path* between each pair of vertices in a tree.

*Proof.* Trees are connected graphs, so, there is a simple path between each pair of vertices. Are they unique?

Assume that for vertices  $x$  and  $y$  there are two simple paths between them. There must exist a vertex  $w$ , where the paths separate, and a vertex  $z$ , where they meet again for the first time. But they form a simple cycle  $w \rightarrow z \rightarrow w$ !

This is a contradiction, b/c trees don't have simple cycles, therefore, our assumption was incorrect, and for any  $x$  and  $y$ , there is no two different simple paths in a tree.  $\square$

**Lemma.** Removing one edge from the edge set of a tree gives a graph with two connected components, each of which is a tree.

*Proof.* By the previous theorem, a removed edge makes the tree disconnected.

When edge  $(u, v)$  is removed, each vertex is either connected to  $u$ , or to  $v$ . So, there are two connected components.

And each connected component is a tree, because we could not introduce cycles by removing the edge  $(u, v)$ .  $\square$

# Properties of trees

**Theorem.** A tree with  $n > 0$  vertices has  $n - 1$  edges.

Tree

Euler formula for  
planar graphs

Spanning trees

Rooted trees

Huffman coding

# Properties of trees

Tree

Properties

Euler formula for  
planar graphs

Spanning trees

Rooted trees

Huffman coding

**Theorem.** A tree with  $n > 0$  vertices has  $n - 1$  edges.

Proof by (strong) induction using the previous lemma.

*Base case:* A tree with one vertex has 0 edges, fine.

*Inductive step: IH:* Assume that for all trees with  $0 < m < n$  vertices, there are  $m - 1$  edges.

Given a tree with  $n$  vertices, remove one edge, getting two connected components  $C_1$  and  $C_2$  with  $k$  and  $n - k$  vertices respectively. By the IH,  $C_1$  and  $C_2$  have  $k - 1$  and  $n - k - 1$  edges. Thus the original tree contained  $(k - 1) + (n - k - 1) + 1 = n - 1$  edges.

**Corollary.** A finite tree with more than one vertex has at least one vertex of degree 1.

Therefore, trees have leaves (terminal vertices).

Spanning trees

Rooted trees

Huffman coding

**Theorem** (Euler formula). Let  $G$  be a connected planar simple graph with  $e$  edges and  $v$  vertices. Let  $r$  be the number of faces in a planar representation of  $G$ . Then

$$v - e + f = 2.$$

# Euler formula for planar graphs

Tree

Properties

Euler formula for  
planar graphs

Spanning trees

Rooted trees

Huffman coding

*Proof.* If there is more than one face, there is an edge separating two faces. Remove it, merging the faces.  $f$  and  $e$  are decreased by one, but  $v - e + f$  remains the same.

Continue, until there is only one face. Then, since there is only one face, there is no simple cycles, so this is a tree.

In the tree, there is at least one vertex with degree 1 (a leaf). Remove it from the tree.  $e$  and  $v$  are both decreased by 1. Therefore,  $v - e + f$  remains the same.

Continue, until there is only one vertex,  $v = 1$ ,  $e = 0$ ,  $f = 1$ :

$$v - e + f = 2$$

In the original graph,  $v - e + f$  was the same. □

# Spanning trees

**Def.** Let  $G$  be a simple graph. A *spanning tree* of  $G$  is a subgraph of  $G$  that is a tree containing every vertex of  $G$ .

# Rooted tree

**Def.** A *rooted tree* is a tree in which one vertex has been designated as *the root* and every edge is directed away from the root.

A node has: the parent node, children, siblings, ancestors, descendants.

A vertex is called a *leaf* if it has no children, otherwise it is called an *internal vertex*.

Huffman coding

**Theorem.** A full  $m$ -ary tree with  $i$  internal vertices contains

$$n = m \cdot i + 1 \quad \text{vertices.}$$

In particular, in binary trees,  $n = 2i + 1$ .

*Proof.* Every vertex, except the root, is the child of an internal vertex. Because each of the  $i$  internal vertices has  $m$  children, there are  $mi$  vertices in the tree other than the root. Therefore, the tree contains  $n = mi + 1$  vertices.  $\square$

# Rooted trees

Tree

Properties

Euler formula for  
planar graphs

Spanning trees

Rooted trees

Huffman coding

**Theorem.** A full  $m$ -ary tree with  $i$  internal vertices contains

$$n = m \cdot i + 1 \quad \text{vertices.}$$

In particular, in binary trees,  $n = 2i + 1$ .

How can we use the theorem?

Note that the number of leaves is  $l = n - i$ .

**Question:** What is the number of internal nodes and the number of leaves in a full binary tree with  $n$  vertices?

# Rooted trees

Tree

Properties

Euler formula for  
planar graphs

Spanning trees

Rooted trees

Huffman coding

*Question:* What is the number of internal nodes and the number of leaves in a full binary tree with  $n$  vertices?

*Solution:*  $n = 2i + 1$ , so the number of internal nodes is

$$i = (n - 1)/2,$$

and the number of leaves is

$$l = n - i = n - (n - 1)/2 = (n + 1)/2.$$

Thus in a large full binary tree, the number of internal nodes is almost the same as the number of leaves.

# Rooted trees

**Question:** Find the least  $n > 0$  such that there exist two trees:  
a full 19-ary tree with  $n$  vertices, and  
a full 32-ary tree with the same number of vertices.

Use the same theorem:

**Theorem.** A full  $m$ -ary tree with  $i$  internal vertices contains

$$n = m \cdot i + 1 \quad \text{vertices.}$$

# Encode a message

Tree

Properties

Euler formula for  
planar graphs

Spanning trees

Rooted trees

Huffman coding

Consider a situation when we are sending messages like this:

*THISISAMESSAGETESTTESTTEST*

Conventional **char** type takes 8 bits. So, every letter is encoded as a bit-string of length 8.

We would like to find a way to efficiently encode the letters of the English alphabet with shorter bit-strings.

# Possible solution

Tree

Properties

Euler formula for  
planar graphs

Spanning trees

Rooted trees

Huffman coding

We encode 26 letters as bit-strings of length 5. Since  $2^5 = 32 > 26$ , this is enough to represent each letter.

$A = 00000$ ,  $B = 00001$ ,  $C = 00010$ , ...

Can we do better if we know how frequently each letter occurs in the message?

Consider using bit strings of different lengths to encode letters.

# Frequencies of letters

Letter	Frequency
A	8.167%
B	1.492%
C	2.782%
D	4.253%
E	12.702%
F	2.228%
G	2.015%
H	6.094%
...	

We can try

$$E = 0$$

$$A = 1$$

$$H = 00$$

$$D = 01$$

$$C = 10$$

$$F = 11$$

$$G = 000$$

$$B = 001$$

Rooted trees

Huffman coding

# Prefix codes

How to resolve the problem? Make a code so that there is no such collisions.

Encode letters so that the bit string for a letter never occurs as the prefix (first part) of the bit string for another letter.

$$E = 0$$

$$A = 10$$

$$H = 110$$

$$D = 1110$$

$$C = 11110$$

...

Codes with this property are called *prefix codes*.

*Input:*

Letter	Frequency
A	8.167%
B	1.492%
C	2.782%
D	4.253%
E	12.702%
F	2.228%
G	2.015%
H	6.094%
...	

Given symbols and their frequencies, our goal is to construct a rooted binary tree where the symbols are the labels of the leaves.

*Huffman coding* is an algorithm that takes as input the frequencies of symbols in a string and produces as output a prefix code that encodes the string using the *fewest possible bits*.

*Output:* prefix code.

Huffman coding

What is the average number of bits used to encode a character?

$$3 \cdot (0.08 + 0.10 + 0.12 + 0.15) + 2 \cdot (0.20 + 0.35) = 2.45.$$

Huffman coding is optimal code in the sense that no binary prefix code for these symbols can encode these symbols using fewer bits.
