Previously, we defined

Def (Divisibility). We say that a *divides* b if there is an integer k such that

$$b = a \cdot k$$
.

We write $a \mid b$ if a divides b. Otherwise, we write $a \nmid b$.

Theorem (The Division Algorithm). Let a be an integer and d a positive integer. Then there are *unique* integers q and r, such that 0 < r < d and

$$a = dq + r$$
.

GCD is a linear combination

Def (GCD).

Theorem (Bezout's Theorem). If a and b are positive integers, then there exist integers s and t such that

$$\gcd(a,b) = sa + tb.$$

Exmaple: gcd(52, 44) = 4

$$6 \cdot 52 + (-7) \cdot 44 = 4$$

So called Extended Euclid's algorithm constructs such s and t, and so proves the theorem. The algorithm is described in the last section of this lecture.

Relative primes (co-primes)

Def (Prime numbers).

Def (Relative primes). a and b are relative primes (or co-primes) if

$$gcd(a, b) = 1.$$

By Bezout's theorem, *a* and *b* are co-primes if and only if there exist *s* and *t* such that

$$sa + tb = 1$$

Multiplicative inverse

Factorization of positive integers

Theorem (Fundamental theorem of arithmetic). Every positive integer n can be written in a unique way as a product of primes

$$n = p_1 \cdot p_2 \cdot \ldots \cdot p_j$$
 $(p_1 \le p_2 \le \ldots \le p_j)$

This product is called prime factorization.

See Lehman and Leighton (p. 67) for the proof.

Congruence

Def. For a positive integer n, a is *congruent* to b modulo n if

$$n \mid (a-b)$$
.

This is denoted

$$a \equiv b \pmod{n}$$
.

Example:

$$8 \equiv 1 \pmod{7}$$

$$15 \equiv 1 \pmod{7}$$

$$8 \equiv 15 \pmod{7}$$

because

$$7 \mid (\underbrace{8-1}_{=7}), \quad 7 \mid (\underbrace{15-1}_{=14}), \quad 7 \mid (\underbrace{15-8}_{=7})$$

Lemma. If $a \equiv b \pmod{n}$, then exists $k \in \mathbb{Z}$ s.t. a = b + kn.

Lemma. Two numbers are congruent modulo n if and only if they have the same remainder when divided by n.

$$a \equiv b \pmod{n}$$
 if and only if $a \operatorname{rem} n = b \operatorname{rem} n$.

Proof: By the division algorithm,

$$a = q_1 n + r_1,$$
 $b = q_2 n + r_2.$
 $a - b = (q_1 - q_2)n + (r_1 - r_2)$

" \Rightarrow ": If $a \equiv b \pmod{n}$ then $n \mid (a - b)$. So $r_1 - r_2 = 0$, the remainders are equal.

"\(\infty\)": If
$$r_1 = r_2$$
, then $n \mid (a - b)$, so $a \equiv b \pmod{n}$.

Modular arithmetic

Congruence

Modular arithmetic

Multiplicative inverse

Addition, subtraction, and multiplication preserve congruence.

Theorem. if
$$a \equiv b \pmod{n}$$
 and $c \equiv d \pmod{n}$, then

$$a+c\equiv b+d\pmod{n}$$
.

 $ac \equiv bd \pmod{n}$.

Theorem. if
$$a \equiv b \pmod{n}$$
 and $c \equiv d \pmod{n}$, then

Exist $x, y \in \mathbb{Z}$ such that a - b = xn and c - d = yn.

$$ac - bd = (b + xn)(d + yn) - bd = n(xd + by + xny)$$

Thus
$$ac \equiv bd \pmod{n}$$
.

GCD is a linear combination

Relative primes

Fundamental theorem of arithmetic

Modular arithmetic

Congruence

Modular arithmetic

Multiplicative inverse

Addition, subtraction, and multiplication preserve congruence. What does it mean practically?

If we have to find *x* such that

$$12^2 \cdot (-11) + 80 \equiv x \pmod{5}$$

We know that

$$12 \equiv 2 \pmod{5},$$

 $-11 \equiv -1 \pmod{5},$
 $80 \equiv 0 \pmod{5}$

Therefore, we are free to substitute 12 with 2, -11 with -1, and 80 with 0:

$$12^2 \cdot (-11) + 80 \equiv 2^2 \cdot (-1) + 0 \equiv 2 \cdot 2 \cdot (-1) \equiv -4 \equiv 1 \pmod{5}.$$

What about division?

Theorem. if a and n are relative primes, i.e. gcd(a, n) = 1, then exists integer a^{-1} called *multiplicative inverse*, such that

$$aa^{-1} \equiv 1 \pmod{n}$$

Proof.

Exist s and t, such that sa + tn = 1. Therefore,

$$sa-1=tn$$

$$sa \equiv 1 \pmod{n}$$

Therefore,
$$a^{-1} = s$$
.

GCD is a linear combination

Relative primes

Fundamental theorem of arithmetic

Modular arithmetic

Congruence

Modular arithmetic

Multiplicative inverse

Corollary. If a and n are relative primes, then there exists a *unique* multiplicative inverse $a^{-1} \in \{1, 2, ..., n-1\}$ such that

$$aa^{-1} \equiv 1 \pmod{n}$$
.

Ok, uniqueness is great, but we need a procedure for finding multiplicative inverses.

Extended Euclid's Algorithm

Let's adapt this algorithm for finding Bezout coefficients *s* and *t*:

$$101 \cdot s + 4620 \cdot t = 1$$

$$101 \cdot s + 4620 \cdot t = 1$$

Run Euclid's algorithm:

$$a_0 = 4620 = 45 \cdot 101 + 75$$

$$a_1 = 101 = 1 \cdot 75 + 26$$

$$a_2 = 75 = 2 \cdot 26 + 23$$

$$a_3 = 26 = 1 \cdot 23 + 3$$

$$a_4 = 23 = 7 \cdot 3 + 2$$

$$a_5 = 3 = 1 \cdot 2 + 1$$

$$a_6 = 2 = 2 \cdot 1$$

$$a_7 = 1$$

Work backwards, to express GCD in terms of $a_1 = 101$ and $a_0 = 4620$:

$$1 = 3 - 1 \cdot 2$$

GCD is a linear combination

Extended Euclid's Algorithm

The other x_i and y_i can be derived using the relations between a_i 's:

$$a_i = a_{i-2} - q_{i-1} \cdot a_{i-1}$$

Euclid's algorithm computes the next remainder, a_i , this way:

$$a_i = a_{i-2} - q_{i-1} \cdot a_{i-1}$$

Two previous remainders are

$$a_{i-2} = x_{i-2} a_0 + y_{i-2} a_1$$

and

$$a_{i}$$

$$a_{i-1} = x_{i-1}a_0 + y_{i-1}a_1$$

$$-1\frac{a_0}{a_0} + y_{i-1}a_i$$

$$a_i = a_{i-2} - q_{i-1} \cdot a_{i-1}$$

$$= x_{i-2} \cdot a_0 + y_{i-2} \cdot a_1 - q_{i-1} (x_{i-1} \cdot a_0 + y_{i-1} \cdot a_1)$$

= $(x_{i-2} - q_{i-1} x_{i-1}) \cdot a_0 + (y_{i-2} - q_{i-1} y_{i-1}) \cdot a_1$

$$= \Big(\underbrace{x_{i-2} - \Big(\frac{a_{i-2} - a_i}{a_{i-1}}\Big) x_{i-1}}_{} \Big) \cdot \underbrace{a_0} + \Big(\underbrace{y_{i-2} - \Big(\frac{a_{i-2} - a_i}{a_{i-1}}\Big) y_{i-1}}_{} \Big) \cdot a_1$$

GCD is a linear combination

Relative primes

Fundamental theorem of arithmetic

Modular arithmetic

Congruence

Modular arithmetic Multiplicative inverse

$$a_i = a_{i-2} - q_{i-1} \cdot a_{i-1}$$

This is how we compute all x_i and y_i up to x_k and y_k :

$$x_{0} = 1 x_{1} = 0 y_{1} = 1 ... x_{i} = x_{i-2} - \underbrace{\left(\frac{a_{i-2} - a_{i}}{a_{i-1}}\right)}_{=q_{i-1}} x_{i-1} y_{i} = y_{i-2} - \underbrace{\left(\frac{a_{i-2} - a_{i}}{a_{i-1}}\right)}_{=q_{i-1}} y_{i-1}$$

In the end, we get two numbers x_k and y_k , so we can express the GCD as a linear combination of a_0 and a_1 :

$$\gcd(\mathbf{a_0}, \mathbf{a_1}) = \mathbf{a_k} = \mathbf{x_k} \cdot \mathbf{a_0} + \mathbf{y_k} \cdot \mathbf{a_1}$$

Extended Euclid's

Algorithm

While computing the sequence of a_i 's with Euclid's algorithm, we eventually produced coefficients

$$x_7 = -35, \qquad y_7 = 1601$$

By construction, they satisfy the equation

$$a_7 = x_7 \cdot \mathbf{a_0} + y_7 \cdot \mathbf{a_1}$$

$$1 = \underbrace{-35}_{=x_7} \cdot \underbrace{4620}_{=a_0} + \underbrace{1601}_{=y_7} \cdot \underbrace{101}_{=a_1}$$

But from the last equation we can find the inverse of 101 modulo 4620, and the inverse of 4620 modulo 101.

Finding a multiplicative inverse

Take this equation and find the multuiplicative inverse of $a_1 = 101$ modulo $a_0 = 4620$.

$$1 = \underbrace{-35}_{=x_7} \cdot \underbrace{4620}_{=a_0} + \underbrace{1601}_{=y_7} \cdot \underbrace{101}_{=a_1}$$

$$1601 \cdot 101 - 1 = 35 \cdot 4620$$

Therefore, by definition of congruence,

$$101 \cdot 1601 \equiv 1 \pmod{4620}$$
.

So, 1601 is a multiplicative inverse of 101 modulo 4620.

We were able to find the inverse, because 101 and 4620 are relative primes, that is, their GCD is equal to 1.
